Reviewing Documents with a Coding Agent

The LaiTeX example paper

Abstract

Writing a paper with a coding agent is fast until the review step. The author reads the compiled PDF, but the agent edits the source, so every comment has to be copied out of the PDF, located in the source and explained again in a chat window. This example paper exists to be reviewed with LaiTeX: open it, select a sentence, leave a comment, and send it to your agent.

1 Introduction

Most technical documents are written in a markup language and read as a PDF. LaTeX [1] and Typst [2] both separate the two: the author edits plain text, a compiler produces pages. Coding agents are good at the first half. They can restructure a section, fix notation everywhere, or rewrite a paragraph in a different tone. They cannot see what the reader sees.

The review loop closes that gap. The reader comments on the rendered page, the agent receives each comment with the quoted text and its surroundings, edits the source, rebuilds, and replies. Section 2 describes the loop and Section 3 estimates what it saves.

2 The review loop

A review round has four steps. The reader selects text and writes a comment. The reader sends all open comments at once. The agent applies them and rebuilds the PDF. The viewer reloads the new PDF at the same position, and each comment shows the agent's reply.

The viewer records comments and requests, and saves only what the reader types in its code editor; the agent decides what to change, and the reader can ask it to commit when the round is done. Table 1 lists who does what.

Step	Reader	Agent
Comment	selects text, writes a note	
Send	presses Cmd+Enter	wakes up
Apply		edits source, rebuilds
Reply	reads the reply in place	writes one reply per comment

Table 1: Division of work in one review round.

3 What it saves

Let n be the number of comments in a round, t_c the time to write one comment, and t_l the time to locate the commented text in the source and describe it to the agent. Reviewing in a chat window costs

$$T_{\text{chat}} = n\,(t_c + t_l), \tag{1}$$

while reviewing on the page costs $T_{\text{page}} = n\,t_c$, because the quote and its context travel with the comment. For a round of twenty comments with $t_l = 30\,\text{s}$, Equation (1) gives ten minutes spent only on pointing at text.

4 Conclusion

Comment where you read, edit where you write, and let the agent move between the two. PDF.js [3] renders the pages; the rest is a small Python server and a skill file that tells the agent how to take part.
